

The AMOS database system

Storing data, one meteor at a time

Mgr. Martin Baláž

2019-04-17

Overview

Contents

objective What are we doing?

motivation Why?

implementation How?

results What have we done?

Objective

- ▶ to build a database system for storing real meteor data
- ▶ it should be
 - web-based** accessible from anywhere
 - comprehensible** we are able to identify interesting events easily
 - autonomous** integrate the entire processing pipeline

Motivation

Current state is a disaster

Motivation

Current state is a ~~disaster~~ suboptimal

- ▶ no unified file format
- ▶ data spread across multiple computers
- ▶ analysis next to impossible
 - ▶ and I badly missed it in diploma thesis

Data

Acquisition

Data are acquired by AMOS cameras

- ▶ **UFOCapture** by SonotaCo
- ▶ **AMOS** by Kvant
 - ▶ will be ready in about two months...

Acquisition

Data are acquired by AMOS cameras

- ▶ **UFOCapture** by SonotaCo
- ▶ **AMOS** by Kvant
 - ▶ will be ready in about two months...
 - ▶ ...for the last three years

Pre-processing

Pre

- ▶ meteor recognition and data extraction
 - ▶ position in the sky
 - ▶ magnitude
 - ▶ angular speed
 - ▶

Retrieval

Currently:

- ▶ UFOCapture launches a `bat` file
- ▶ mail transfer via SMTP (e-mail)
- ▶ processed by `charon`

Proposal:

- ▶ video capturing software forwards data to a daemon
- ▶ sent over HTTP in a POST request

Retrieval

Currently:

- ▶ UFOCapture launches a **bat** file
- ▶ mail transfer via SMTP (e-mail)
- ▶ processed by **charon**

Proposal:

- ▶ video capturing software forwards data to a daemon
- ▶ sent over HTTP in a POST request
- ▶ we need an **API**
 - ▶ station submits a new **Sighting**
 - ▶ website retrieves a list of **Meteor**s
 - ▶ daemon periodically computes **Meteor** data
 - ▶ other internal use (maps, analyses...)

Processing

Data need to be **validated** and **processed**

- ▶ remove invalid data (false detections, ...)
- ▶ compute **Meteor**s from multiple **Sighting**s
- ▶

Storage

At this point data are ready to be stored

- ▶ in a **structured** and **semantic** way
- ▶ consistency is **enforced** at all times
- ▶ auxiliary data
 - ▶ housekeeping
 - ▶ statistics

Data retention

To prevent problems down the line, we should

- ▶ keep **all** raw data available
- ▶ never delete anything (unless provably incorrect)
- ▶ enable raw data re-processing
 - ▶ for example to import data from an offline station

Housekeeping

Def: Data of low scientific value but high operational importance

- ▶ environment
 - ▶ temperature
 - ▶ humidity
 - ▶ pressure
 - ▶ ...

Housekeeping

Def: Data of low scientific value but high operational importance

- ▶ environment
 - ▶ temperature
 - ▶ humidity
 - ▶ pressure
 - ▶ ...
- ▶ network
 - ▶ system uptime
 - ▶ network connection
 - ▶ UPS status
 - ▶ ...
- ▶ displayed on dashboard

Database

The database

Problem: We need a way to visualize and comprehend the data

The database

Problem: We need a way to visualize and comprehend the data **Solution:** A database and a simple web interface

- ▶ provides a basic framework for data operations
- ▶ much more user-friendly than a bare directory listing
- ▶ much easier to retrieve, sort and analyze the data

Design

Underlying data are well-structured and suitable for an **object-relational** database

- ▶ we require

text files PostgreSQL SQLite MySQL

Design

Underlying data are well-structured and suitable for an **object-relational** database

- ▶ we require
 - ▶ full ACID compliance

text files PostgreSQL SQLite MySQL

Design

Underlying data are well-structured and suitable for an **object-relational** database

- ▶ we require
 - ▶ full ACID compliance
 - ▶ free

PostgreSQL SQLite MySQL

Design

Underlying data are well-structured and suitable for an **object-relational** database

- ▶ we require
 - ▶ full ACID compliance
 - ▶ free
 - ▶ able to scale well

PostgreSQL

MySQL

Design

Underlying data are well-structured and suitable for an **object-relational** database

- ▶ we require
 - ▶ full ACID compliance
 - ▶ free
 - ▶ able to scale well
 - ▶ decoupled from the rest of the system

PostgreSQL

Design

Underlying data are well-structured and suitable for an **object-relational** database

- ▶ we require
 - ▶ full ACID compliance
 - ▶ free
 - ▶ able to scale well
 - ▶ decoupled from the rest of the system
 - ▶ I like it

PostgreSQL

ORDBMS

- ▶ data are stored in **relations** (tables)
- ▶ each column stores the same **property**
- ▶ each row stores a single **entity** (object)
- ▶ each object has an identifier (primary key)
- ▶ fields may point to other tables (foreign keys)
- ▶ data are accessed and manipulated using a query language

ORDBMS

```
SELECT "id", "timestamp", "magnitude" \  
FROM "meteors" \  
WHERE "timestamp" BETWEEN "2019-04-16 15:00:00" AND "2019-04-17 09:00:00" \  
ORDER BY "magnitude" ASC LIMIT 5;
```

ORDBMS

```
SELECT "id", "timestamp", "magnitude" \  
FROM "meteors" \  
WHERE "timestamp" BETWEEN "2019-04-16 15:00:00" AND "2019-04-17 09:00:00" \  
ORDER BY "magnitude" ASC LIMIT 5;
```

```
356, "2019-04-17 03:45:10", -5.8  
728, "2019-04-17 04:14:23", -3.2  
456, "2019-04-16 23:56:04", -2.7  
908, "2019-04-17 01:23:45", -2.5  
854, "2019-04-16 21:58:35", -2.2
```

Models

We should be able to naturally translate the real world to models

- ▶ Meteor
- ▶ Sighting
- ▶ Station
- ▶ Subnetwork
- ▶ Country

Model Sighting

Describes the **sighting** of a single meteor by an AMOS camera

- ▶ identifier
- ▶ observed projected position on the sky
- ▶ three coordinates
 - ▶ azimuth
 - ▶ altitude
- ▶ at three moments
 - ▶ beginning
 - ▶ maximum brightness
 - ▶ end
- ▶ maximum apparent magnitude

Model Sighting – extras

- ▶ miscellaneous computed information
 - ▶ arc length
 - ▶ duration
 - ▶ Sun and Moon info
 - ▶ position
 - ▶ elongation
 - ▶ magnitude
- ▶ visualisation
 - ▶ real photograph from AMOS
 - ▶ corresponding simulation (?)

(link)

Model Meteor

Describes the actual **event**, an atmospheric entry of a meteoroid particle

- ▶ **timestamp**
- ▶ true geographic location
 - ▶ again, four coordinates
 - ▶ **timestamp**
 - ▶ **latitude**
 - ▶ **longitude**
 - ▶ **altitude**

Model Meteor

Describes the actual **event**, an atmospheric entry of a meteoroid particle

- ▶ **timestamp**
- ▶ true geographic location
 - ▶ again, four coordinates
 - ▶ **timestamp**
 - ▶ **latitude**
 - ▶ **longitude**
 - ▶ **altitude**
 - ▶ at three moments
 - ▶ beginning
 - ▶ maximum brightness
 - ▶ end

Model Meteor – auxiliary data

- ▶ **true trail length**
 - ▶ this is not well-defined
- ▶ computed maximal **absolute magnitude** (least-squares)
- ▶ **visualisation**
 - ▶ KML file for Google Earth
 - ▶ online map (OpenLayers)

(link)

Visualisation

Overview

We have implemented a website in Python/Django

- ▶ webserver + CRUD operations
- ▶ administration interface (courtesy of Django)
- ▶ REST framework

System in operation

- ▶ Dashboard
- ▶ Meteor list
- ▶ Sighting list
- ▶ Example of a sighting
- ▶ Example of a meteor
- ▶ Example of a meteor path

admin!

Thank you for your attention

Above all else, show the data.

Edward R. Tufte
The Visual Display of Quantitative Information, 1983
